

# 07. Assessment of dehydration

Last update: 2022-09-14

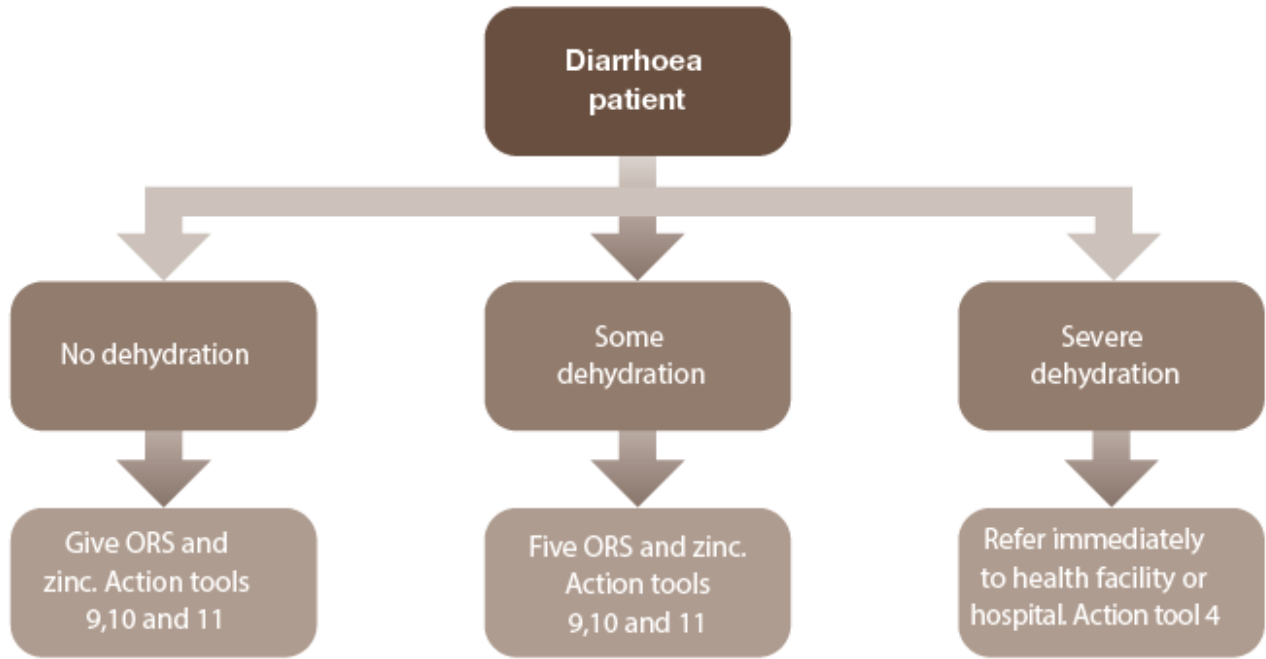

## Overview

- Patients with diarrhoea, especially children, can lose a lot of fluid from their bodies and suffer dehydration.
- Dehydration can cause very severe illness and sometimes death, especially in association with acute watery diarrhoea and cholera.

## How to assess whether a patient has dehydration, and its extent

Dehydration stage	Signs	Treatment
No dehydration	Skin recovers its shape normally when pinched; thirst has subsided; urine has been passed; the pulse is strong.	Oral rehydration solution (ORS) at home; zinc supplements for children up to 15 years of age.
Moderate dehydration	Restlessness and irritability; sunken eyes, dry mouth and tongue, increased thirst; skin recovers its normal shape slowly when pinched; reduced urine; decreased tears; depressed fontanel (soft membranes on head) in infants.	ORS and very close surveillance; zinc supplements for children up to 15 years of age.
Severe dehydration	Lethargy or unconsciousness; very dry mouth and tongue; skin recovers shape very slowly when pinched ("tenting"); weak or absent pulse; low blood pressure; minimal or no urine.	In a health facility or in a hospital: IV therapy plus antibiotics plus ORS; zinc supplements for children up to 15 years of age.

After the assessment, and according to the degree of dehydration, the following actions should be taken:

***Signs of dehydration***

- Sunken eyes
- Dry mouth
- Lethargic/weak
- Skin pinch returns slowly
- Little or no urine
